To: Bob Klinefelter, P.E. VTrans Structures Project Manager

Project #: 58643.00

From: Aaron Guyette, P.E. Project Manager Ryan Barnes, P.E. Senior Structural Engineer Re: Royalton BF 0147(29) NECR over VT 14 Alternatives Analysis

Background

The Royalton BF 0147(29) Project consists of providing a safe alternative to address the existing deficiencies with the New England Central Railroad (NECR) Crossing over VT Route 14 in Royalton, Vermont. The bridge is Bridge No. 35.01 at Milepost 35.01 on NECR Roxbury Subdivision and is located at Milemarker 5.131 on VT Route 14. The project was initiated by VTrans as an emergency project following a vehicle impact to the existing bridge in July 2021. The bridge crossing has low vertical clearance (12'-1"), substandard roadway width (single lane) with a severe "S" curve, and the bridge is in poor condition with frequent vehicle impacts. No guardrail is present to protect vehicles from the bridge abutments. The intent of this memo is to establish the purpose and need statement and design criteria and analyze alternatives to make a recommendation that will provide a safe crossing to address the current deficiencies.

Purpose and Need Statement

The purpose of the project is to construct a safe highway-railroad crossing that meets current design standards with a long, low-maintenance service life. The project is needed because the existing bridge crossing has limited vertical and horizontal roadway clearance, sight distance, and horizontal alignment that do not meet current design standards. The bridge is in poor condition and has had many impacts resulting in damage to the steel superstructure and abutments.

Design Criteria

The design standards for this project that are pertinent to the alternative analysis are summarized in the table that follows. The minimum standards referenced in the following table are for Major Collector State Highway based on an ADT of 3600vpd and a design speed of 40 mph. Design standards for a reduced design speed of 30mph are also provided where different from 40 mph.

Vermont Route 14 alternatives are based on the Vermont State Design Standards and AASHTO's A Policy on Geometric Design of Highways and Streets. It is important to note that this portion of VT 14 is a high use / high priority bicycle corridor in the VTrans Bicycle Corridor Priority Map. The project team will investigate appropriate bicycle accommodations to incorporate into the project during the Preliminary Design Phase.

Alternatives Discussion

1. Alternative 1 – Do Nothing

This alternative consists of leaving the bridge and roadway in its current state and carries with it no initial construction cost. The substandard roadway vertical and horizontal clearances, sight distances, and horizontal alignment all remain unchanged. The poor bridge condition and susceptibility to future vehicle impacts all remain as concerns for maintenance and serviceability of the bridge. The bridge abutments remain as fixed obstructions within the clear zone. This alternative does not meet the purpose and need of the project.

2. Alternative 2 – Bridge Replacement

This alternative consists of removal and replacement of the existing bridge with a new bridge, designed to provide roadway clearances and geometry that meet geometric and structural design standards. The most prudent location for a new bridge replacement is to the south of the existing bridge. This location will allow the necessary modifications to the roadway curvature to occur within the existing right-of-way as well as allow the majority of the bridge construction to occur prior to removal of the existing structure. There is also an area to the south of the existing bridge, west of the track, that could be used as a staging area. This area is in the existing right-of-way and could be used to facilitate a lateral bridge slide as part of accelerated bridge construction. A new bridge will provide a minimum of 14'-6" vertical clearance to meet the minimum design standard.

Bridge Replacement Structure Type

The anticipated replacement superstructure type is an open-deck steel through girder structure. This superstructure type is capable of the required span length with the least depth (measured from top of rail to bottom of girder) compared to other viable superstructure types and will provide the required vertical clearance, without excessive impacts to the roadway and railroad limits. Weathering steel could be used for the superstructure in this location which will eliminate the initial cost and future maintenance associated with painting

or otherwise coating. An open-deck through girder bridge will also be a cost-effective superstructure type that will be constructable by a wide range of contractors and have relatively low future maintenance costs.

Two different structure layout alternatives were considered; one skewed layout (skewed approx. 52-degrees), and one with no skew. The skewed layout would have the abutments and bridge end skewed to the rail alignment and span approximately 70'-0" between centerlines of bearing (with a 30mph roadway layout). The alternative with no skew would span approximately 105'-0" (with a 30mph roadway layout) to provide the necessary clearances. The skewed alternative will have lesser material costs over the alternative with no skew, although there are several disadvantages summarized below:

- The fabrication of the girders and floor system components at the end of the bridge are much more complicated and customized. A heavily skewed end floor beam, variable length stringers, and bent connection plates are needed. Additionally, the crossties at the skewed end would bear partially on a stringer and partially on a backwall or ballast.
- Due to the heavy skew, each girder will deflect differently at a perpendicular section, creating out-of-plane bending stresses. Out-of-plane bending stresses increase the probability of fatigue cracking over the design life of the bridge.
- The abutments and foundation elements are longer and more costly than an alternative without a skew.
- A skewed structure is more difficult and costly to install by means of a lateral slide than an alternative without a skew.

Because of the preceding disadvantages without significant advantages, a non-skewed bridge structure layout is recommended.

It is anticipated that the substructures will consist of deep foundation elements (drilled shafts, micropiles, or driven H-Piles) with a precast concrete cap. These substructures would be installed during short-term track closures in advance of the superstructure installation. The particular deep foundation element will be determined following the subsurface investigations. It is also anticipated that soldier pile retaining walls would be constructed to allow initial installation of the piles and a top-down installation of the lagging to occur during new roadway construction.

Roadway Horizontal and Vertical Alignment

Roadway and bridge layouts, and roadway profiles were developed both with 30mph and 40mph VT-14 roadway design speeds. Maximum superelevation of 6% is used for both 30mph and 40mph design speeds due to the presence of intersecting roads (Vesper Road). Drawings for both alternatives are provided in Appendix A and the following summarizes the advantages and disadvantages.

a. Alternative 2A – 30mph Roadway Design Speed

Advantages:

- A shorter bridge with less superstructure cost is required as compared to a 40mph alternative.
- Stopping sight distance will meet standards of a 30-mph collector for vehicles traveling northbound and southbound.
- Vertical alignment will minimize impacts and work to Vesper Road.
- Existing drainage patterns are maintained.

Disadvantages:

- A slower design speed is required than areas directly to the north and south of the project area and appropriate advancing warning signs will have to be installed. The design speed may be 10mph lower than legal speed without a design exception (VSS Section 5.3)
- Intersection sight distance for Vesper Road is substandard when looking to the south (viewing northbound traffic). The AASHTO standard (Table 9-9, Case B2 Right Turn from Stop) calls for a minimum of 290-feet, where the configuration of the roadway geometry and the bridge provides for 203-feet, or 70% of the desired sight distance. The intersection sight distance is less than desirable; however, the stopping sight distance is adequate. Cars exiting Vesper Road may cause an inconvenience for mainline motorists, but the proposed configuration will not cause a safety concern.

b. Alternative 2B – 40mph Roadway Design Speed

Advantages:

• This alternative proposes a design speed equal to the posted speed limit directly to the north and south of the project area, eliminating the need for a lower advisory speed while traveling under the bridge.

Disadvantages:

- A longer bridge is required with greater superstructure cost as compared to a 30mph alternative.
- Impacts to Vesper Road will be greater than 30-mph alternative requiring additional roadway reconstruction and the need for permanent retaining wall support structures. The additional work adds both time and expense to the project and results in increased impacts from an environmental and utility perspective.
- Limits of road work will extend further along VT Route 14 to maintain standard approach grades and the vertical clearance under the new bridge.

Intersection sight distance for Vesper Road is substandard when looking to the south (viewing northbound traffic). The AASHTO standard (Table 9-9, Case B2 Right Turn from Stop) calls for a minimum of 385-feet, where the configuration of the roadway geometry and the bridge provides for 155-feet, or 40% of the desired sight distance. The intersection sight distance is less than desirable and does not allow for adequate stopping sight distance for mainline vehicles approaching Vesper Road from the south, meaning that vehicles exiting Vesper Road and entering VT 14 may be at risk for collision with vehicles traveling northbound along VT 14. This condition will present a safety hazard that is worse than the current condition for vehicles exiting Vesper Road.

Railroad Horizontal and Vertical Alignment

Altering the railroad horizontal alignment was considered as a means to improve track geometry and/or aid in construction phasing. Raising the track grade to obtain the required vertical clearance is necessary with a bridge replacement alternative. An off-alignment railroad alternative would allow the new (higher grade) track to be constructed with minimal interruption to train service. However, an off-alignment alternative would also have significant right-of-way and environmental impacts and resulting in undesirable track geometry on the west side and undesirable impacts to Vesper Road on the east side.

A bridge replacement alternative will require raising the track grade approximately 2-feet to obtain the necessary 14'-6" vertical clearance along VT-14. It is anticipated that track reconstruction or re-profiling will extend approximately 800-feet north and south of the bridge to tie the new, higher grade to the existing track grade.

Construction Phasing

To facilitate raising the track grade associated with a bridge replacement alternative, it's anticipated that raising the track grade at the north and south ends of the approaches would occur under short-term track closures with a temporary abrupt transition down to the grade of the existing bridge. Also, under short-term track closures the new bridge substructures would be constructed with track being removed and reset as necessary. A new bridge superstructure would likely be constructed offline on temporary abutments and then set into place during an extended short-term track closure with associated approach track grade adjustments immediately north and south of the bridge. Prior to the extended short-term track closure, VT Route 14 would be closed to allow the existing bridge to be removed and the area to be filled to construct a new rail embankment. Following the extended short-term track closure, the area under the new bridge would be excavated, new retaining wall lagging installed, and the new VT Route 14 roadway to be constructed underneath the new bridge.

Interstate 89, between Exits 2 and 3, roughly parallels the section of VT-14 with Bridge No. 35.01 and provides a convenient detour with adequate capacity and functionality. There are also detour routes for local traffic on Town Highways.

3. Alternative 3 – Bridge Replacement with NECR Owned Bridge

NECR owns a ballasted deck steel through girder bridge that could be used as a replacement structure for Bridge No. 35.01. The bridge is 63'-0" long between centerlines of bearing, with no skew, and has a superstructure depth (from top of rail to bottom of girder) of approximately 4'-2". As discussed under Alternative 2, a significantly longer non-skewed bridge is required to obtain the necessary horizontal clearances and roadway alignment. Additionally, the depth of this ballasted deck structure is greater than the open deck structure discussed under Alternative 2, which would necessitate a significant amount more rail and roadway approach work.

If it were desired to adapt this bridge to fit the skewed structure layout, the modifications would be significant and require new end floor beams, cutting and shortening several floor beams, and many new connections. Additional superstructure depth may be required to obtain the track superelevation, and some of the skewed bridge disadvantages described under Alternative 2 would apply as well. The condition and structural capacity of the structure would need to be evaluated to ensure that it would meet the need of the project.

The non-skewed bridge of Alternative 3 does not meet the purpose of this project with regards to horizontal alignment and clearance. The challenges involved with adapting this existing bridge to fit a skewed structure layout are substantial without corresponding benefits. The design life of the superstructure under this alternative is uncertain and therefore also does not meet the purpose of this project.

4. Alternative 4 – Bridge Removal and Construction of At-Grade Crossing

This alternative consists of removing the existing bridge structure and raising the grade of VT-14 to allow for an at-grade rail crossing. This alternative eliminates the initial and future maintenance costs associated with a new bridge. There are construction and maintenance costs with an at-grade crossing pertaining to the track and crossing surface, signals, gate arms, and detection equipment, although it's anticipated that these costs will be less than that of a new bridge. There are several disadvantages associated with initiating a new rail crossing, summarized as follows:

- An additional crossing creates a potential conflict point between vehicles and rail cars creating a significant safety hazard for users of VT-14.
- An additional crossing impacts the operations of NECR and interrupts traffic flow along VT-14. There are currently three highway-rail crossings within approximately one mile north of the bridge and one crossing within approximately one mile south of the bridge along NECR.
- This particular crossing would be highly skewed to meet the roadway geometry, which may restrict motorist's ability to detect oncoming trains and be a safety hazard for motorcycles and bicycles with wheels getting caught in the space between rail and crossing surface.
- An at-grade crossing creates an unfavorable profile along VT Route 14 in that it will occur along a superelevated curve within the tracks. Constructing this would likely result in a substandard superelevation transition within the roadway.

- This crossing would, for both alignment alternatives, be placed within 100 ft of an intersecting roadway which increases potential for conflicting vehicular movements.
- Both alignment alternatives for an at-grade crossing require significant amounts
 of fill material to raise the roadway to the existing track elevation. This will extend
 the limits of work farther along the mainline, alter existing drainage patterns and
 cause greater environmental impacts.

Roadway Horizontal and Vertical Alignment

Roadway layouts and profiles for the at-grade crossing alternative were developed both with 30mph and 40mph roadway design speeds which maintain the same horizontal alignments as proposed in Alternatives 2A and 2B. Drawings for both alternatives are provided in Appendix A. The preceding section summarized several disadvantages with an at-grade crossing, and below are advantages and disadvantages particular to the 30mph and 40mph design speeds that were analyzed.

a. Alternative 4A – 30mph Roadway Design Speed

Advantages:

- Preferrable roadway profile for an at-grade crossing as there is a smaller (51°) skew from the tracks.
- Exceeds standard for intersection sight distance and stopping sight distance for a 30-mph design speed.

Disadvantages:

- Slower speed through crossing with advanced warning signs needed.
- An at grade crossing presents a significant safety concern.

b. Alternative 4B – 40mph Roadway Design Speed

Advantages:

- Alternative will maintain a design speed closer to the existing posted speed limit.
- Exceeds standard for stopping sight distance for a 40-mph design speed.

Disadvantages:

- Less preferrable roadway alignment as it creates a greater skew (62°) from the tracks. This skew between the tracks and the roadway creates a safety hazard for bicyclist crossing the tracks as the gap between rail and pavement will be greater than the 30-mph alternative.
- An at grade crossing presents a significant safety concern.

Railroad Horizontal and Vertical Alignment

The railroad horizontal and vertical alignment would remain essentially unchanged from the existing alignment because there are not currently any deficiencies and lowering the track to make the highway-rail at-grade crossing is not necessary.

Construction Phasing

A roadway alignment to the south of the existing bridge would be used to allow the at-grade crossing to be constructed largely without conflicting with VT-14. It is anticipated that a short-term closure, or at a minimum lane closures of VT-14 would be necessary to tie the at-grade crossing into the existing roadway. It is also anticipated that short term closures of the railroad would be necessary to construct the at-grade crossing.

Opinion of Probable Construction Cost (Concept-Level)

Opinions of Probable Construction Costs were developed for the alternatives considered. The costs include only the initial construction cost and exclude items such as right-of-way and engineering costs, and future maintenance costs. The costs are based on recent bid history or supplier quotes where applicable (increased to cover installed cost). The opinions of probable construction cost for each alternative are provided in the Alternatives Comparison Matrix and included in Appendix B.

Alternatives Comparison Matrix

Evoluation Criteria	<u>Alternative 1 –</u> <u>Do Nothing</u>		2 – Bridge æment	<u>Alternative 3 – Bridge</u> <u>Replacement with NECR</u> <u>Owned Bridge</u>	<u>Alternative 4 – Bridge Removal and</u> <u>Construction of At-Grade Crossing</u>

*Alternative does not meet the purpose of this project; therefore an opinion of probable construction cost is not provided.

Recommendation

VHB Recommends Alternative 2A – Bridge Replacement with a 30mph Roadway Design Speed. The reasons for this recommendation are discussed in this memo and summarized below.

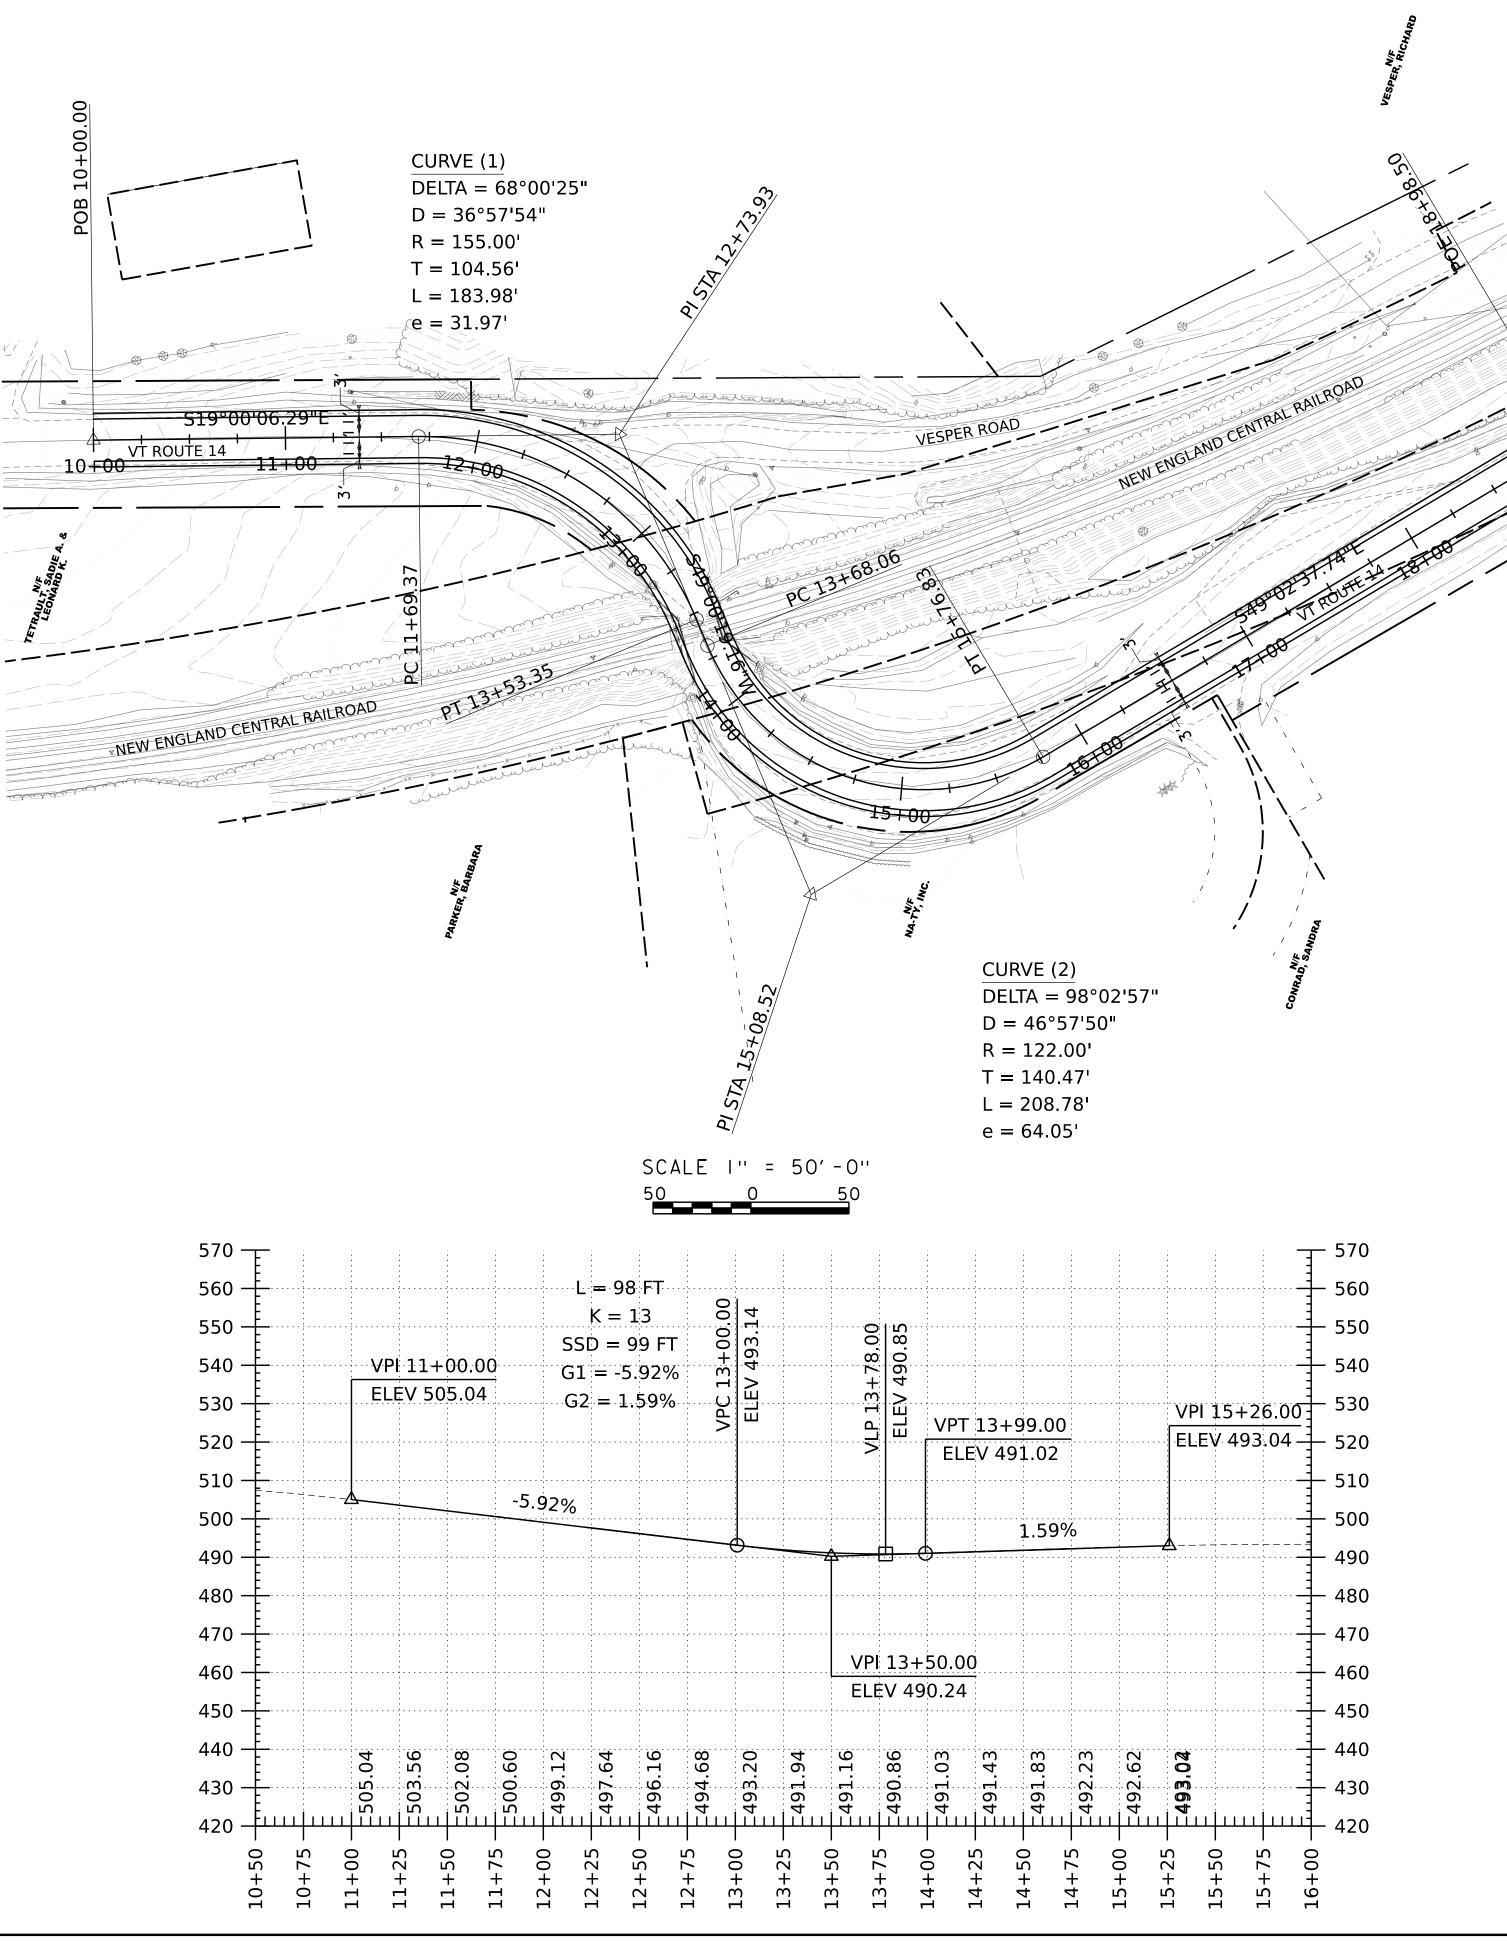

- A bridge replacement as described in this memo will provide the necessary vertical and horizontal roadway clearances along VT-14. A new structure will have a long service life with low maintenance and a decreased probability of future vehicle impacts. A grade separated crossing will eliminate safety concerns associated with an at-grade crossing and will not impede vehicle flow along NECR or VT-14.
- The 30mph bridge replacement alternative provides a balance between roadway speed and functionality, roadway safety with bridge length and cost, and overall project impacts.
- Alternatives 4A and 4B Bridge Removal and Construction of At-Grade Crossing (30mph and 40mph) will create an additional potential conflict point between vehicles and rail cars, which along with the skew of the crossing and placement near a roadway intersection (Vesper Road) is a significant safety concern. An additional at-grade crossing also impedes traffic flow and operations for both NECR and VT Route 14. For these reasons, Alternatives 4A and 4B are not recommended.
- Alternative 1 Do Nothing and Alternative 3 Bridge Replacement with NECR Owned Bridge do not meet the purpose and need of the project and therefore are not recommended.
